

**Presentation of the *Second Big
Challenge Symposium - The Big
Challenge of Cosmological
Understanding: Gravitation, Dark
Matter and Dark Energy. Towards
New Scenarios***

Christian Corda

July 26, 2010

Associazione Scientifica Galileo Galilei, Via Bruno Buozzi 47 - 59100 PRATO,
Italy

- **This Symposium is devoted to the Memory of Lev Kofman June-17-1957-November-12-2009**

The accelerated expansion of the universe that is today observed suggests that cosmological dynamics is dominated by the so-called Dark Energy field which provides a large negative pressure. This is the standard picture, in which such new ingredient is considered as a source of the *right hand side* of the field equations. It should be some form of non-clustered non-zero vacuum energy which, together with the clustered Dark Matter, drives the global dynamics. This is the so-called “*concordance model*” (Λ CDM) which gives, in agreement with the Cosmic Microwave Background Radiation (CMBR), dim Lyman Limit Systems (LLS) and type Ia supernovae (SNeIa) data, a good framework to understand the today observed Universe. However, it presents several shortcomings as the well known “*coincidence*” and “*cosmological constant*” problems [1]. An alternative approach is to change the *left hand side* of the field equations, and check if observed cosmic dynamics can be achieved by extending general relativity [2, 3, 4, 5, 6]. In this different context, it is not required to search candidates for Dark Energy and Dark Matter, which till now have not been found. Rather, one can only stand on the “*observed*” ingredients: curvature and baryon matter, to

account for the observations. Considering this point of view, one can think that gravity is not scale-invariant. Such an assumption opens a room for alternative theories to be introduced [7, 1, 9]. In principle, the most popular Dark Energy and Dark Matter models can be achieved by considering $f(R)$ theories of gravity [2]-[9], where R is the Ricci curvature scalar.

In this picture, even the sensitive detectors for gravitational waves like bars and interferometers (i.e. those which are currently in operation and the ones which are in a phase of planning and proposal stages) [10] could, in principle, be important to confirm or rule out the physical consistency of general relativity or of any other theory of gravitation. This is because, in the context of Extended Theories of Gravity, some differences between General Relativity and the alternative theories can be pointed out as far as the linearized theory of gravity is concerned [11, 12, 13].

In particular, it has been recently shown that the interferometric detection of gravitational waves will be the definitive test for General Relativity or alternatively a strong endorsement for Extended Theories of Gravity [13].

The goal of this Symposium is to obtain a tapestry of the present status of theory and observations concerning Gravitation and Dark Universe.

Acknowledgements

The Associazione Scientifica Galileo Galilei and the Institute for Basic Research have to be thanked for supporting this proceeding and the whole *Second Big Challenge Symposium*.
